after 2 weeks
status

- installed on June 13th (closed up box around 3:30pm)
- camera module died at 5:22pm (~1 hour after we moved the linear stage; no beam at that time; perhaps connector mechanical connection lost?)
- started getting beam at 8pm; thermocouple readout seemed to be working
- thermocouple readout board started going wonky (temp below ambient, then negative, alternating with zeros) about 10am on the 14th, then died completely (all zeros always) at 5pm on the 17th
  - this implies that Pb blocking view of scintillator is not sufficient
- lost communication with rpi sometime since 10am on the 18th (try power cycle)
