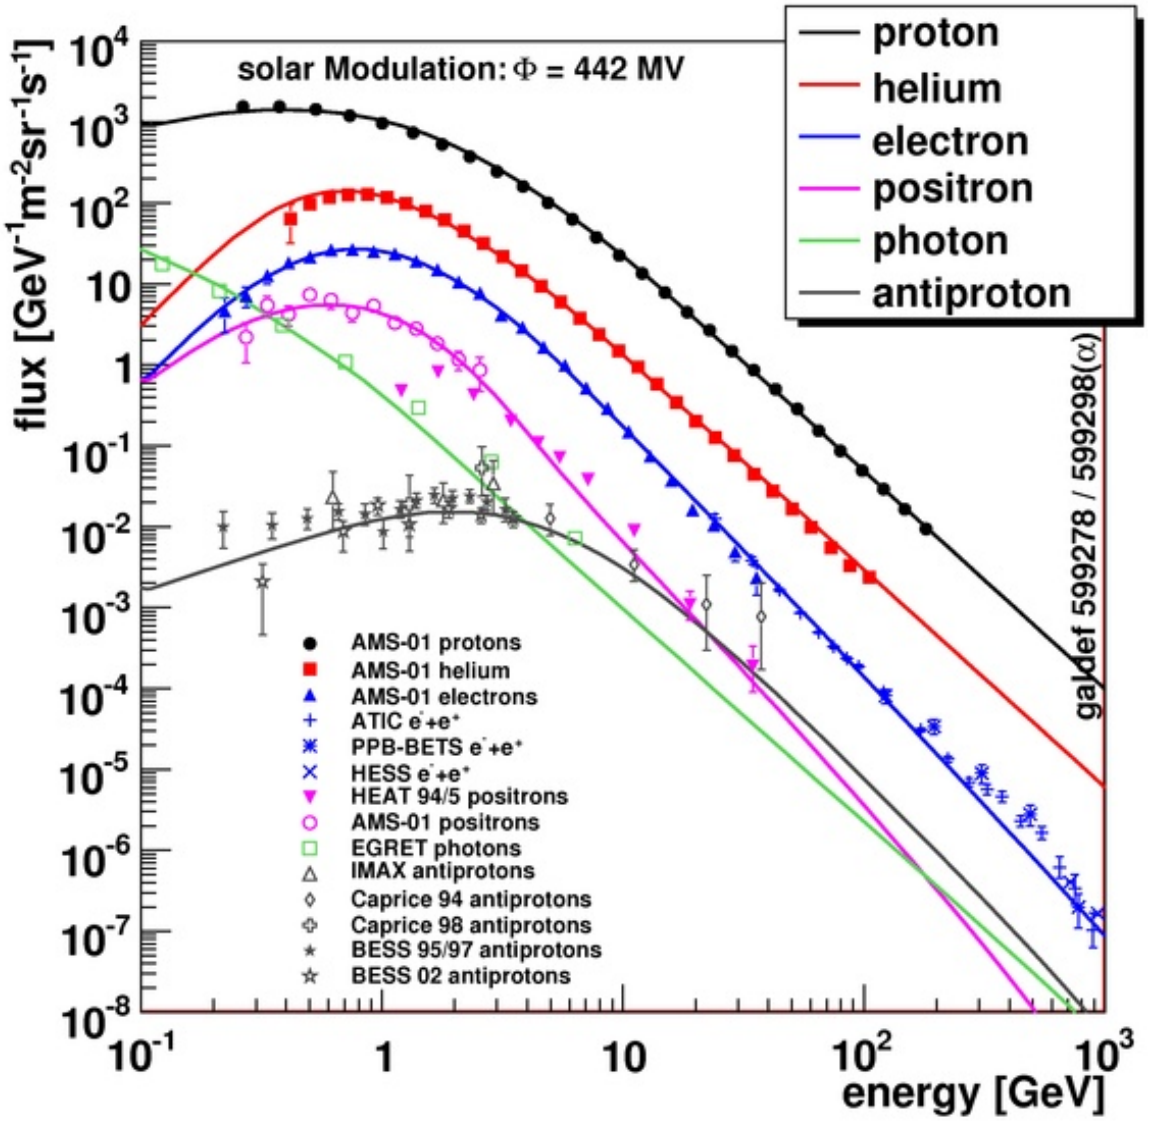
Outline

Why are antideuterons interesting?

How to measure them?

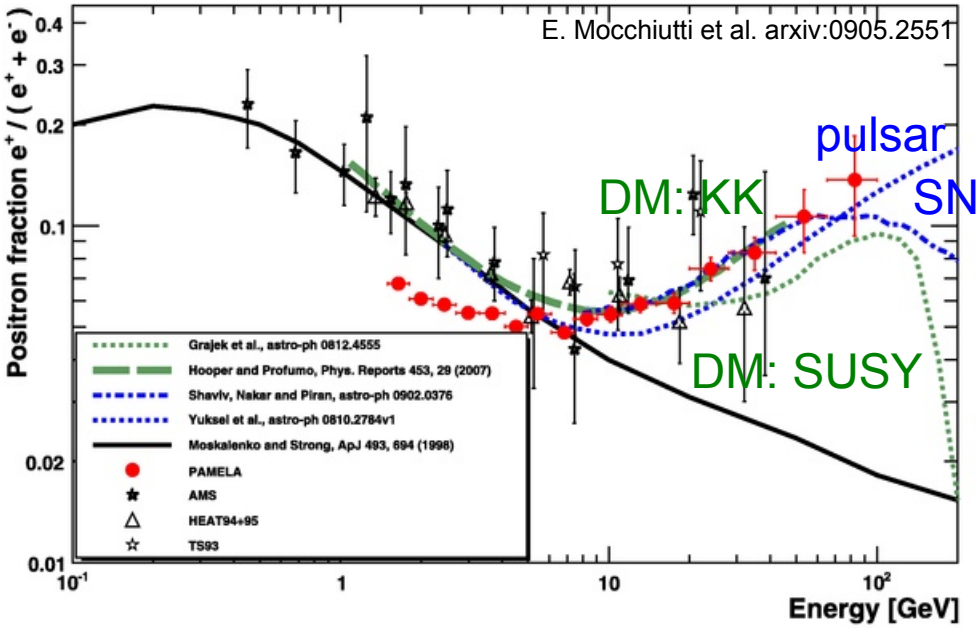
cosmic rays
antideuteron physics
GAPS concept
GAPS prototype instrument

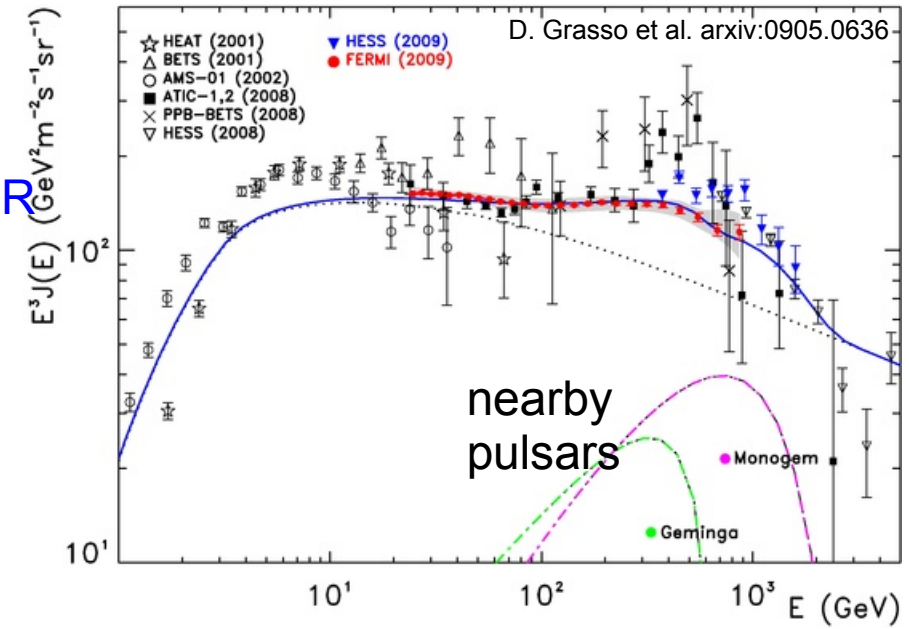
Cosmic rays in the GeV to TeV range



- in general good agreement of models and data
- what we already learned:
  - particle physics
  - interstellar medium
  - astronomical objects
  - …
- small fluxes with no primary astronomical source are especially sensitive to new effects

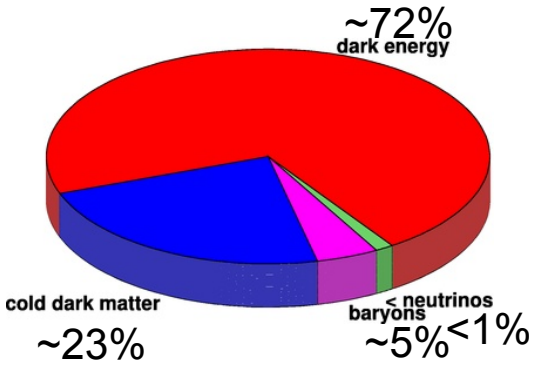
Positron fraction & electron flux





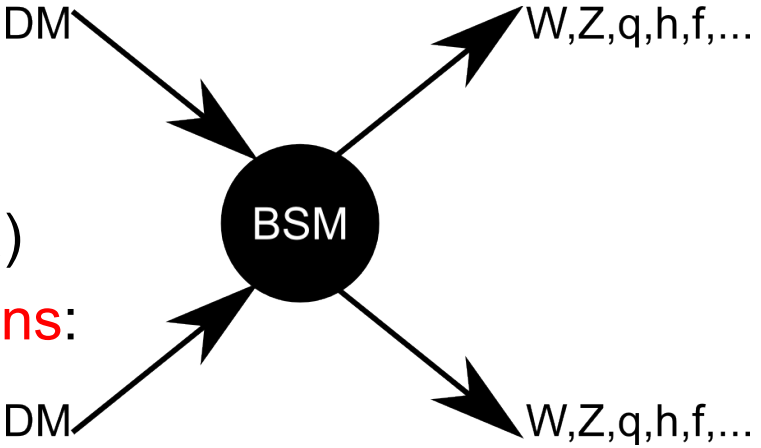
- unexplained features in positron and electron spectra
- proposed theories:
  - γ-ray pulsars can produce electron and positrons via pair production in the magnetosphere
  - positrons and electrons can also be accelerated in PWN or SNR shocks
  - dark matter self-annihilation

Dark matter



- evidence for dark matter exists in many different fields
- BUT we do not know its nature
- different search approaches: direct and indirect: here cosmic rays

dark matter annihilation



- different popular scenarios:
  - Supersymmetry: neutralino (majorana)
  - Kaluza-Klein universal extra dimensions: 1st excitation of photon (boson)
- requires boost factors to explain $e^{+/-}$ fluxes
- indirect dark matter searches are especially sensitive to extra contributions in the antiparticle spectra

Drawbacks...

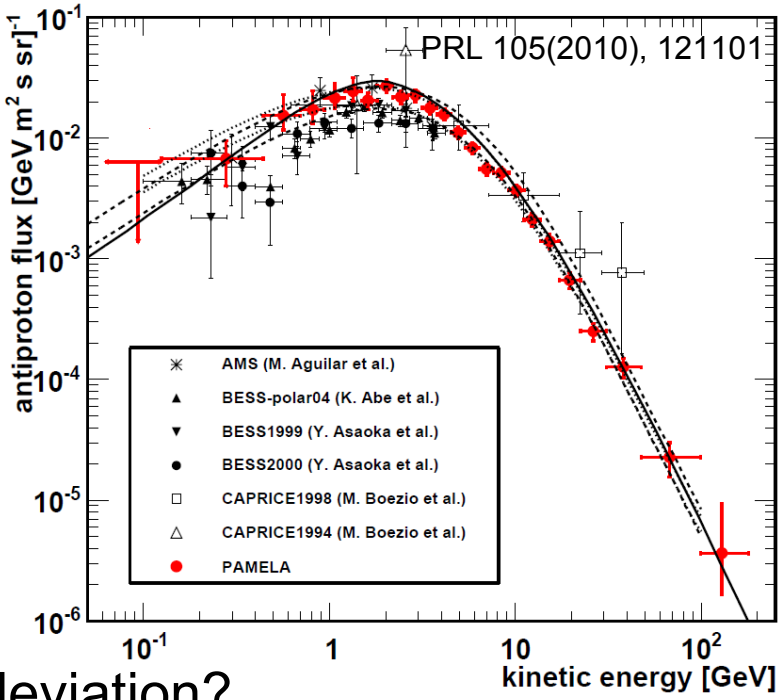
Drawbacks exist for astronomical interpretations:

Are pulsars really able to produce enough electrons and positrons?

Drawbacks exist also for dark matter interpretations:

- observed deviations are relatively small
- boosting mechanisms are needed

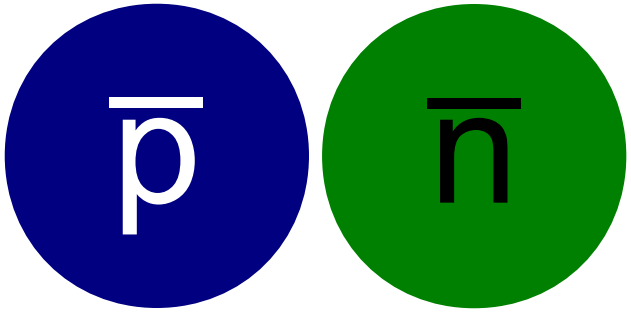
Hard to disentangle the different contributions!

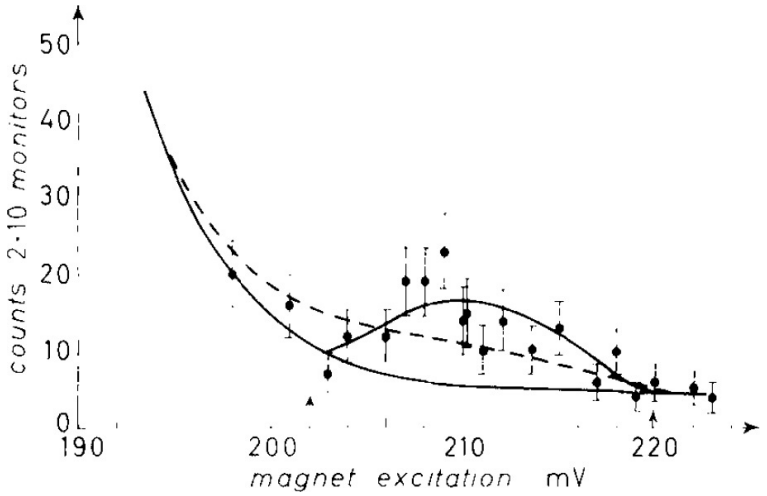


Further questions:

- Is the experimental data well understood (large rejections are needed)?
- Why do antiprotons do not show a deviation?
- Are propagation models well understood?

Antideuterons





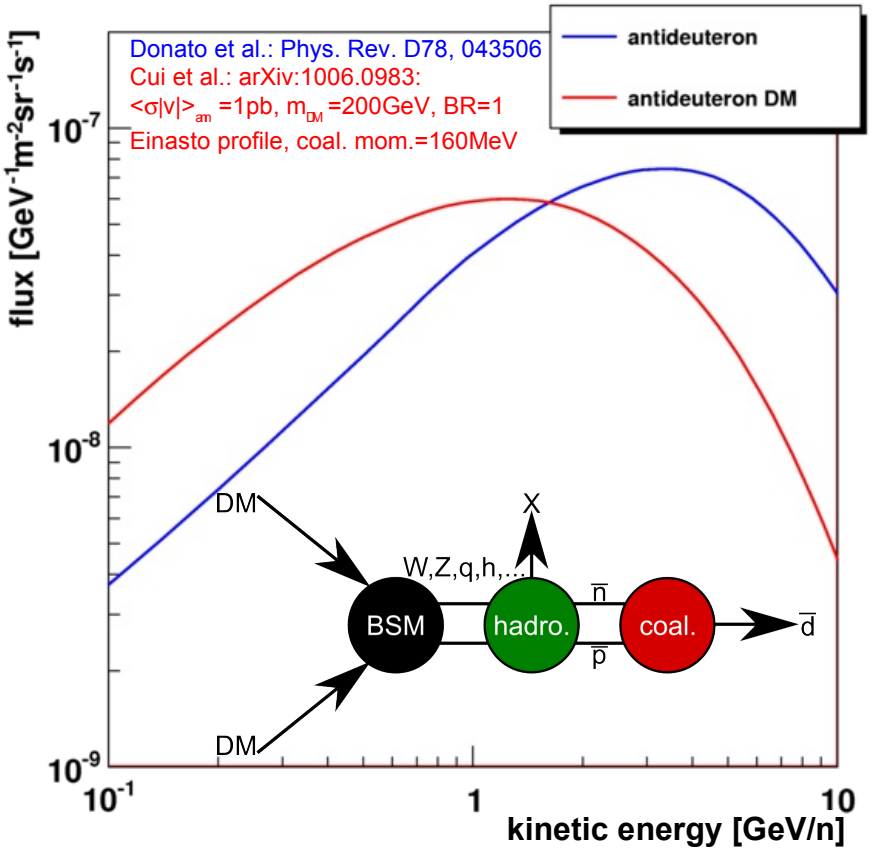
- deuterons are the nuclei of heavy water and antideuterons are the corresponding antimatter (q=-1,m=1876MeV, s=1)
- antideuterons were discovered in 1965 at CERN and Brookhaven and were the first real antimatter ever discovered

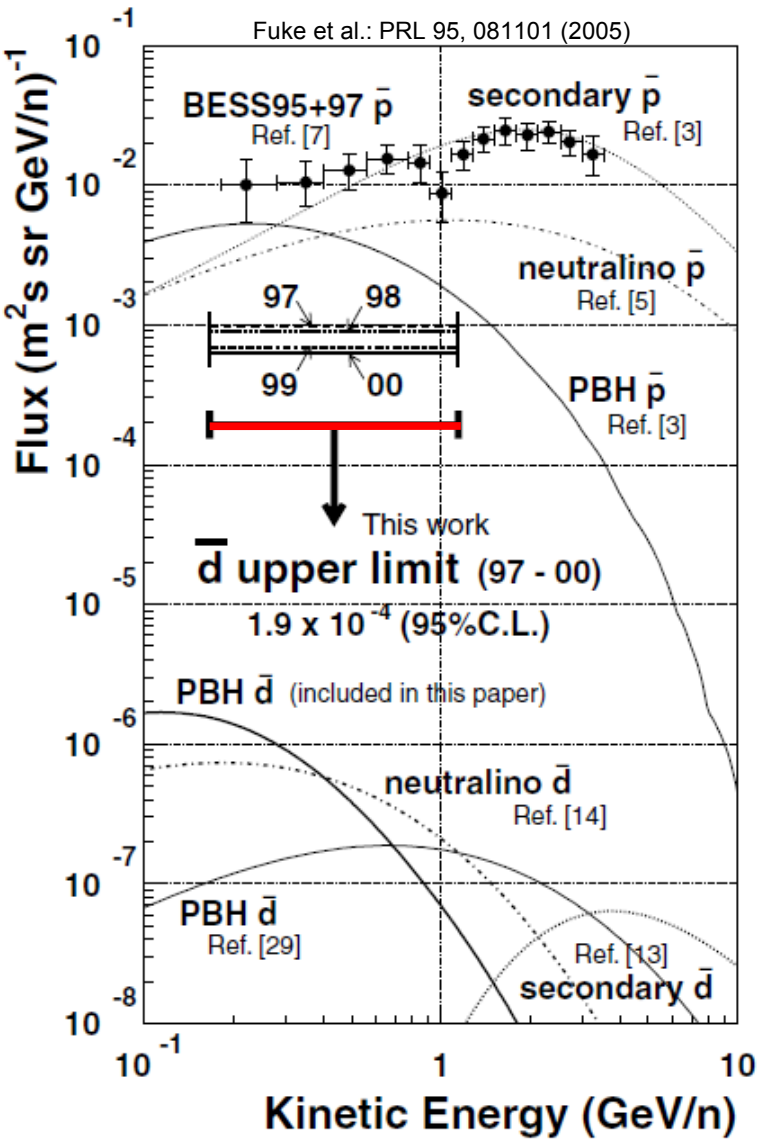
Cosmic rays

- antideuterons have never been detected in cosmic rays
- antideuteron production is understood and it should form in the galactic disk from the collisions of protons, alphas and antiprotons with Hydrogen and Helium IS gas
- if the antiproton and antineutron coalescence momentum is below 160MeV (ALEPH)
- understanding of jet structure is important for precise predictions

[arXiv:0803.264, arXiv:0908.1578]

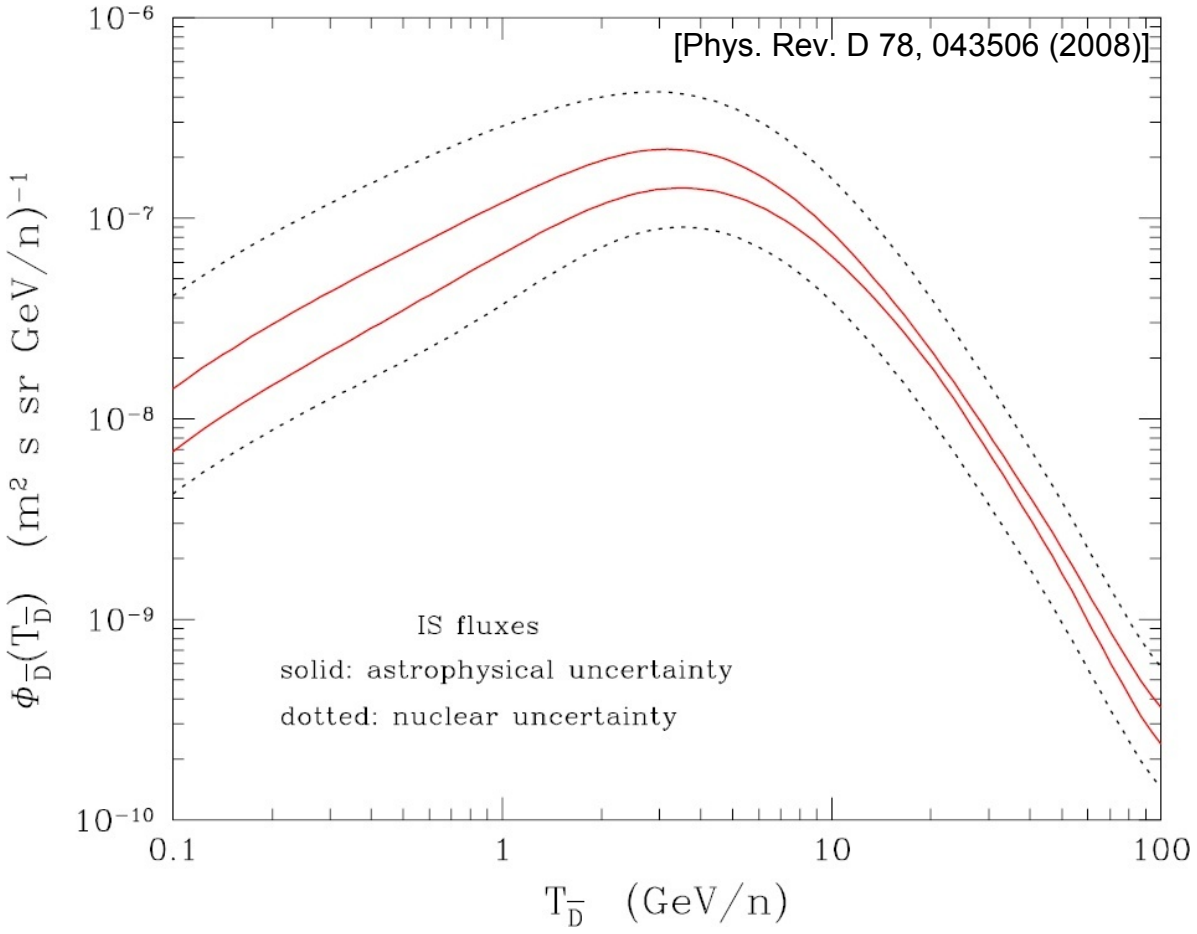
Antideuterons and dark matter





- antideuterons have high production threshold for p-IS
- generic model with dark matter self-annihilation (here W^+W^-) show different shape (consistent with antiproto flux!)
- predicts large signal over background for low-energy antideuteron signals

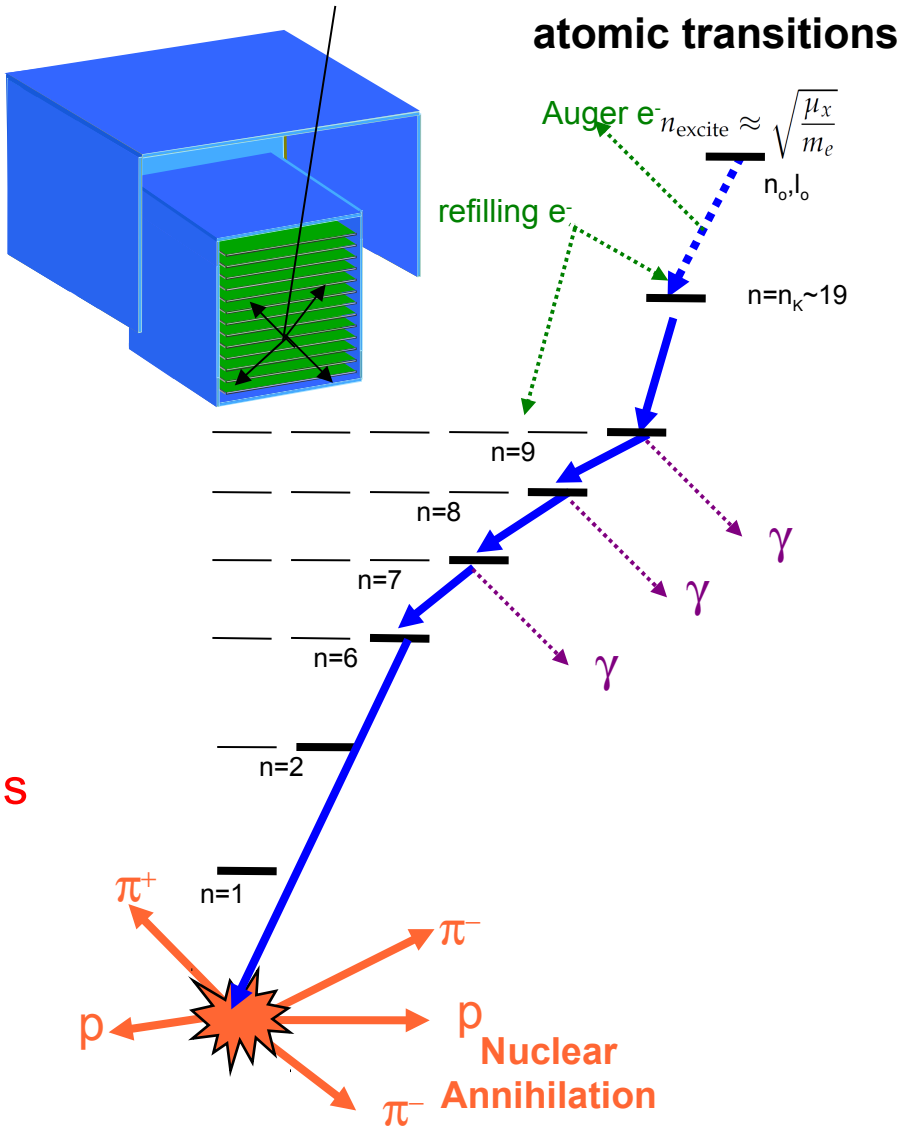
Antideuteron uncertainties



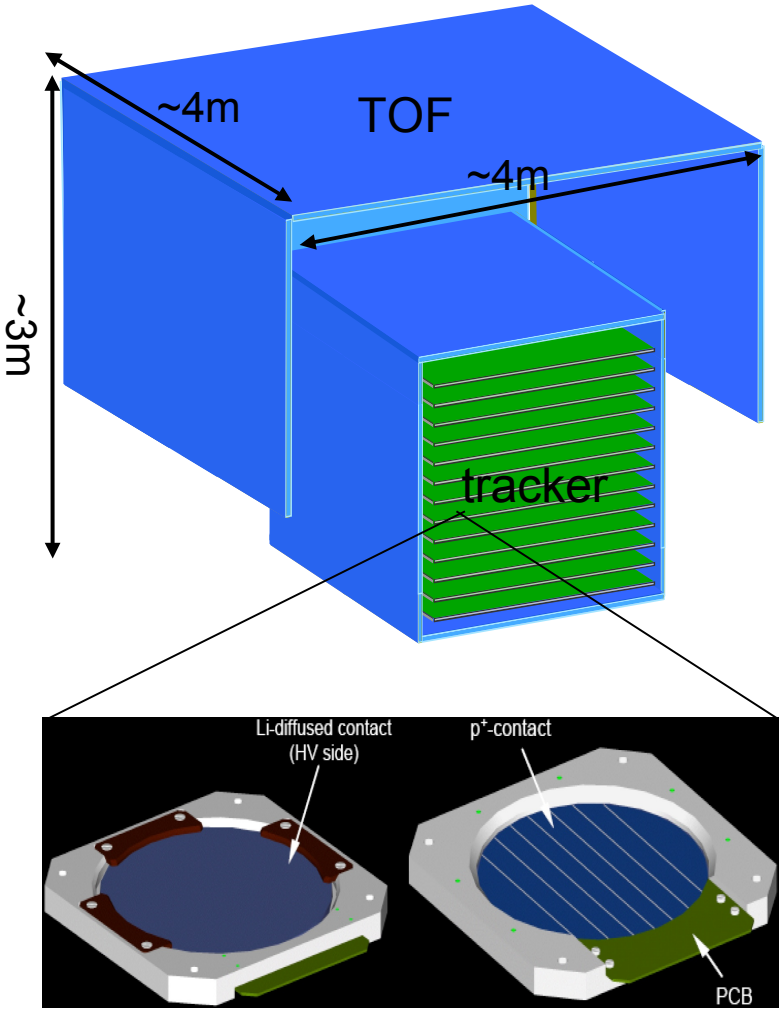
- **nuclear uncertainties:** production cross-section and coalescence momentum
- **propagation uncertainties:** fit of all propagation parameters shows degeneracy, such that the average uncertainty is about 50%
- in the following: plotted background flux is the mean of these uncertainties

Antideuteron identification

- antideuteron slows down and stops in material
- large chance for creation of an excited exotic atom (E_{kin} ~E_I)
- deexcitation:
  - fast ionisation of bound electrons (Auger)
    → complete depletion of bound electrons
  - Hydrogen-like exotic atom (nucleus+antideuteron) deexcites via characteristic x-ray transitions
- nucleus-antideuteron annihilation: pions and protons
- exotic atomic physics quite well understood (tested in KEK 2004/5 testbeam)



GAPS concept



GAPS consists of two detectors (accep.: ~2.7m²sr):

Si(Li) tracker:

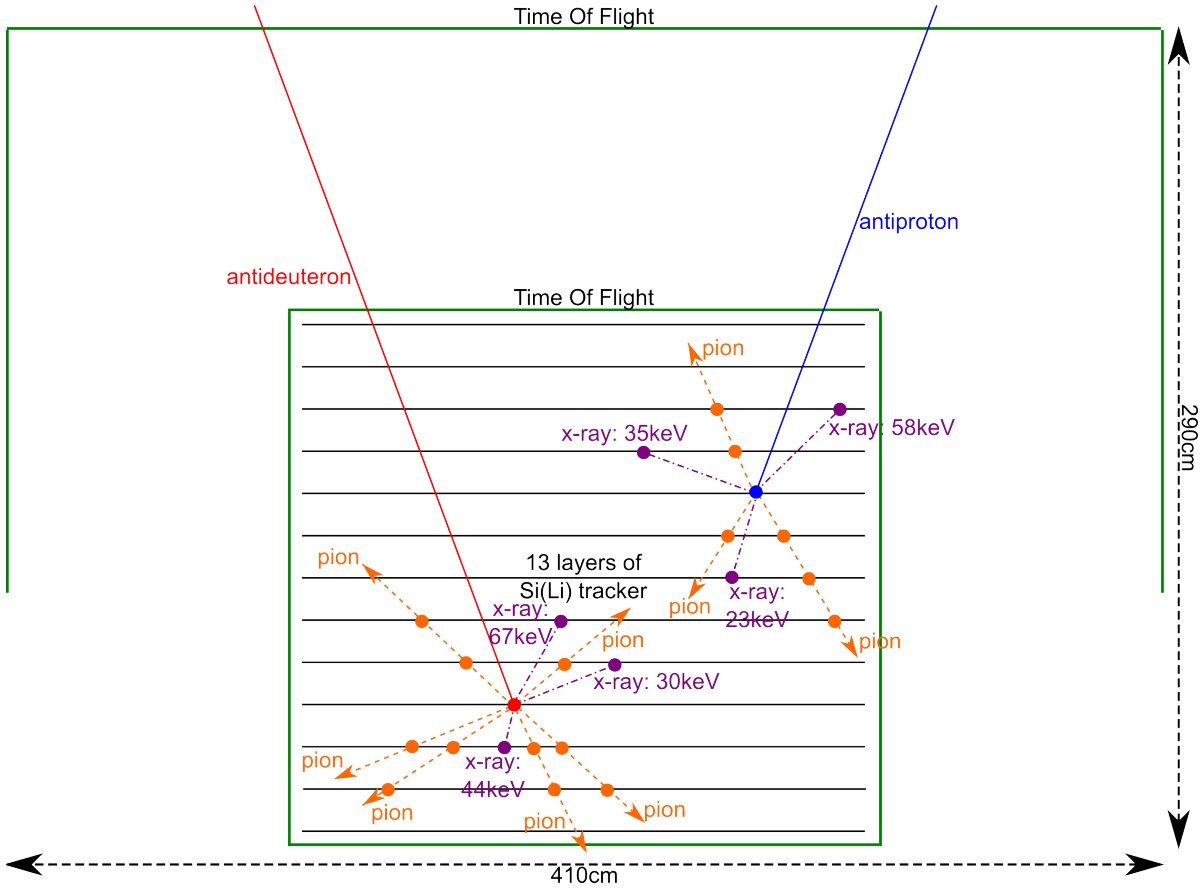
- Si(Li) tracker:13 layers composed of Si(Li) wafers
- relatively low Z material (2/3mm,escape fraction ~20keV)
  → target and detector
- Lithium doped Silicon detectors for a good x-ray resolution
- circular modules segmented into 8 strips, ~8cm² each
  → 3D particle tracking
- 270 per layer (total: ~3500)
- timing: ~50ns
- dual channel electronics
  5-200keV: X-rays (resolution:~2 keV)
  0.1-200MeV: charged particle

Time of flight and anticoincidence shield:

- plastic scintillator with PMTs surrounds tracker
- track charged particles
- velocity and charge measurement

Scientific balloon flights (bGAPS) planned from Antarctica in 2016

Backgrounds



GAPS needs a very reliable particle identification:

- identification uses:
  - TOF velocity and tracks
  - charge |Z|
  - depth in tracker
  - x-rays from deexcitation
  - pions and protons from annihilation

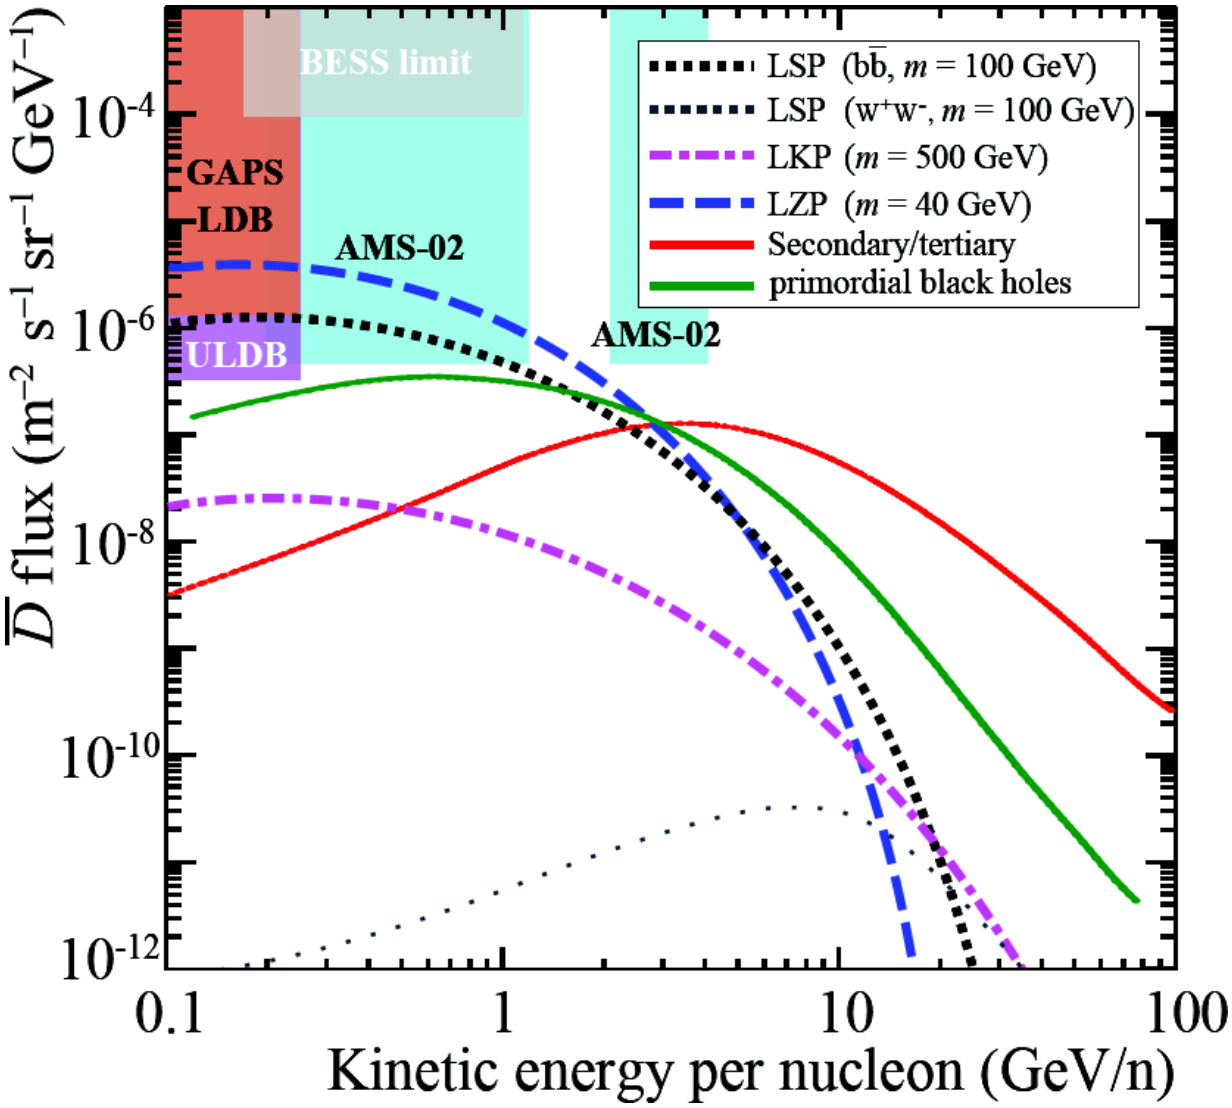
- important background sources for antideuteron events:
  - antiprotons
  - primary cosmic rays in coincidence with cosmic x-rays
  - atmospheric production of antideuterons
  - etc...needs to studied in great detail

GAPS antideuteron sensitivity

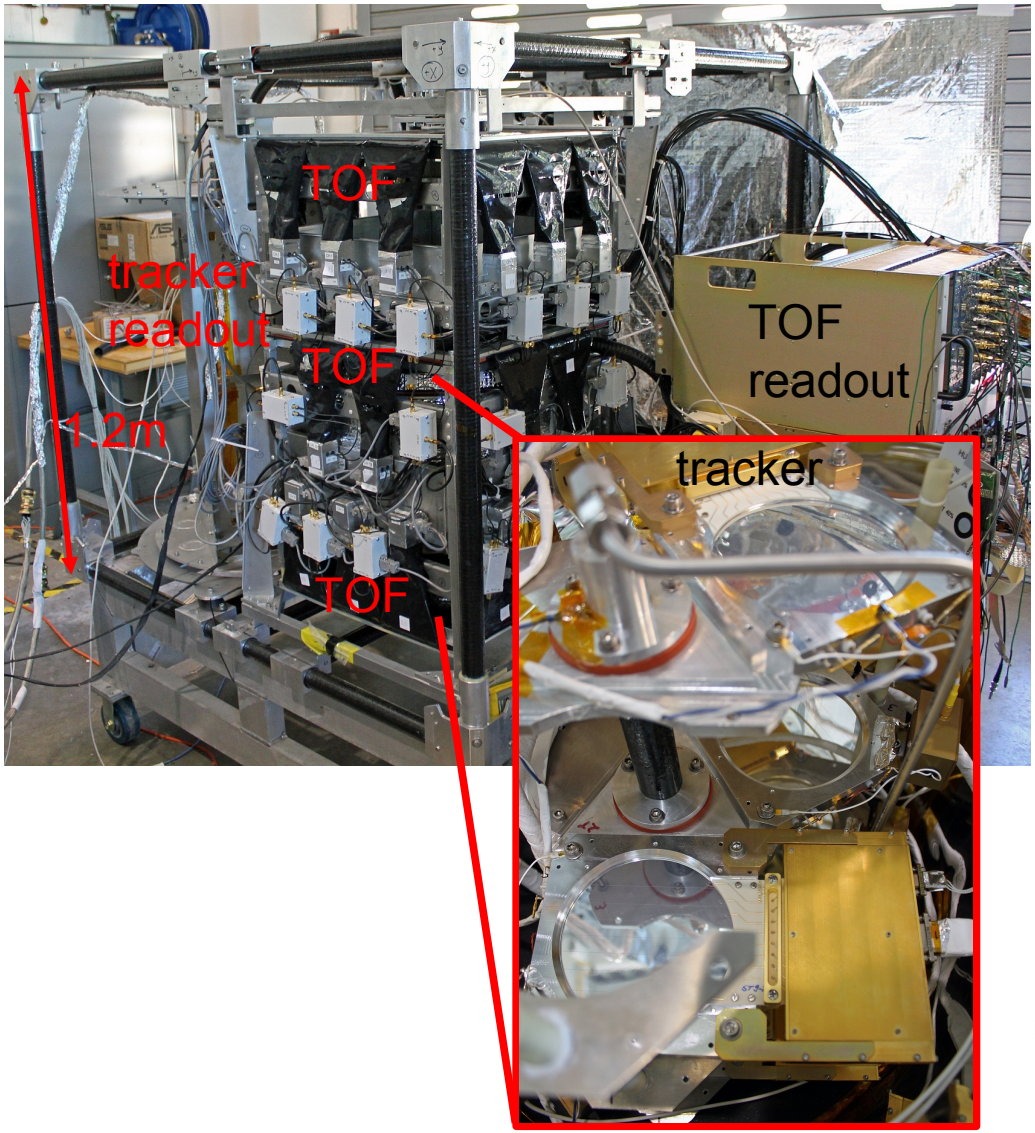
- GAPS need small geomagnetic cut-off
  → therefore (ultra) long duration balloon flights from South Pole are planned: 60 (300) days

- different scenarios give reasonable antideuteron fluxes within sensitivity:
  - Supersymmetry
  - Kaluza-Klein UED
  - Warped extra dimensions
  - primordial black holes

- synergy with direct searches and neutrino telescopes:
  GAPS probes complementary dark matter regions!



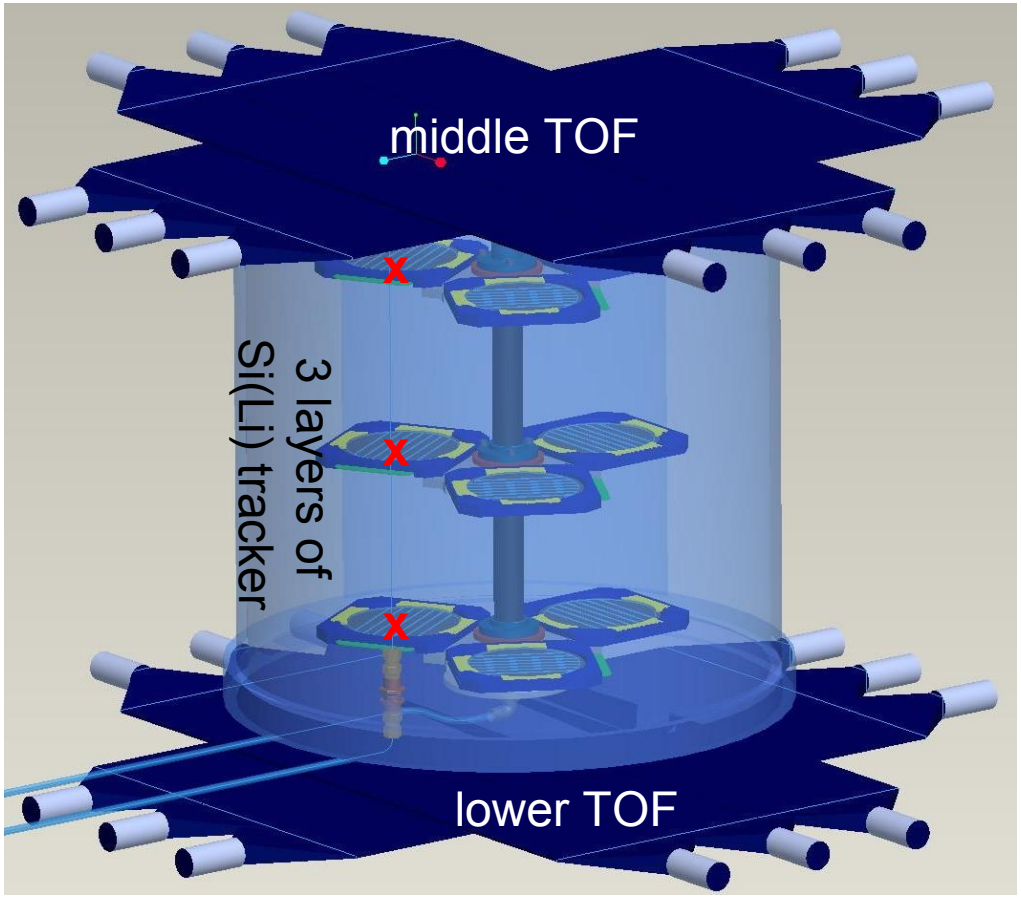
Prototype experiment

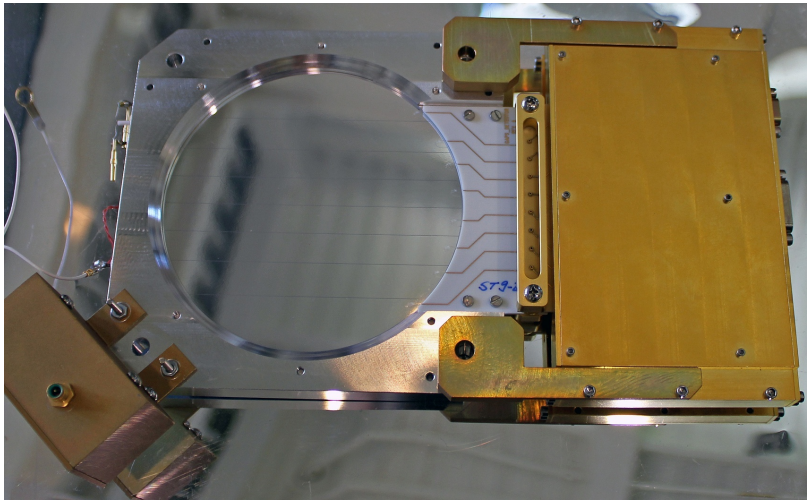


Prototype GAPS (pGAPS) goals:

- demonstrate stable, low noise operation of the detector components at float altitude and ambient pressure.
- demonstrate the Si(Li) cooling approach and verify thermal model
- measure incoherent background level in a flight like configuration.

Si(Li) tracker

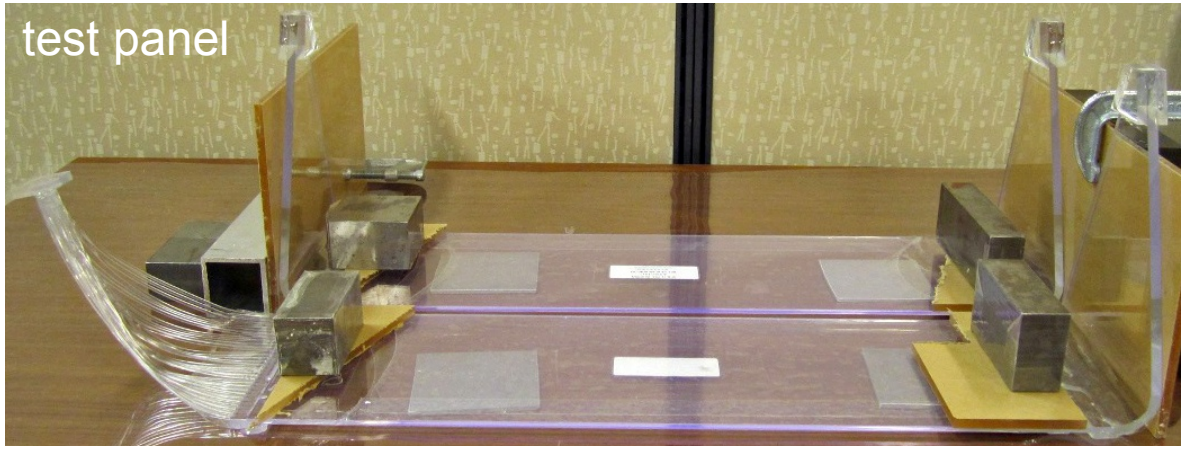


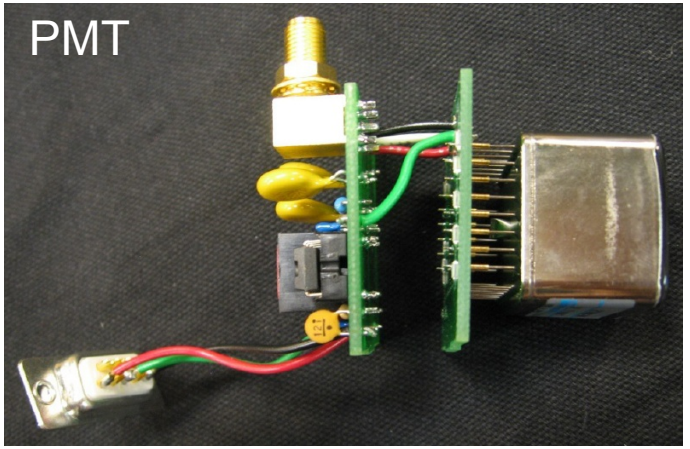


- 6 commercial Semikon detectors (5 currently installed)
- 94mm diameter and 4mm/2.5mm thick, 8 strips
- operation at ambient pressure during flight (8mbar) and in N_2 atmosphere on ground
- cooling system has to deliver ~-35°C
- N+: Lithium contact
- P+: Boron implanted (strips)

- closed-loop fluid pumping system (Fluorinert)
- space radiator

Time of flight system





- 3 planes of TOF
  1 plane consists of 3×3
  (2×2 in the middle) crossed panels
  1 panel has 2 PMTs
  = 16 panels and 32 PMTs
- 3mm scintillator from Bicron (BC-408)
- Hamamatsu R-7600 PMT
- timing resolution: 500ps
- charge resolution: 0.35e
- MOP value: ~15 photo electrons
- angular resolution: 8°

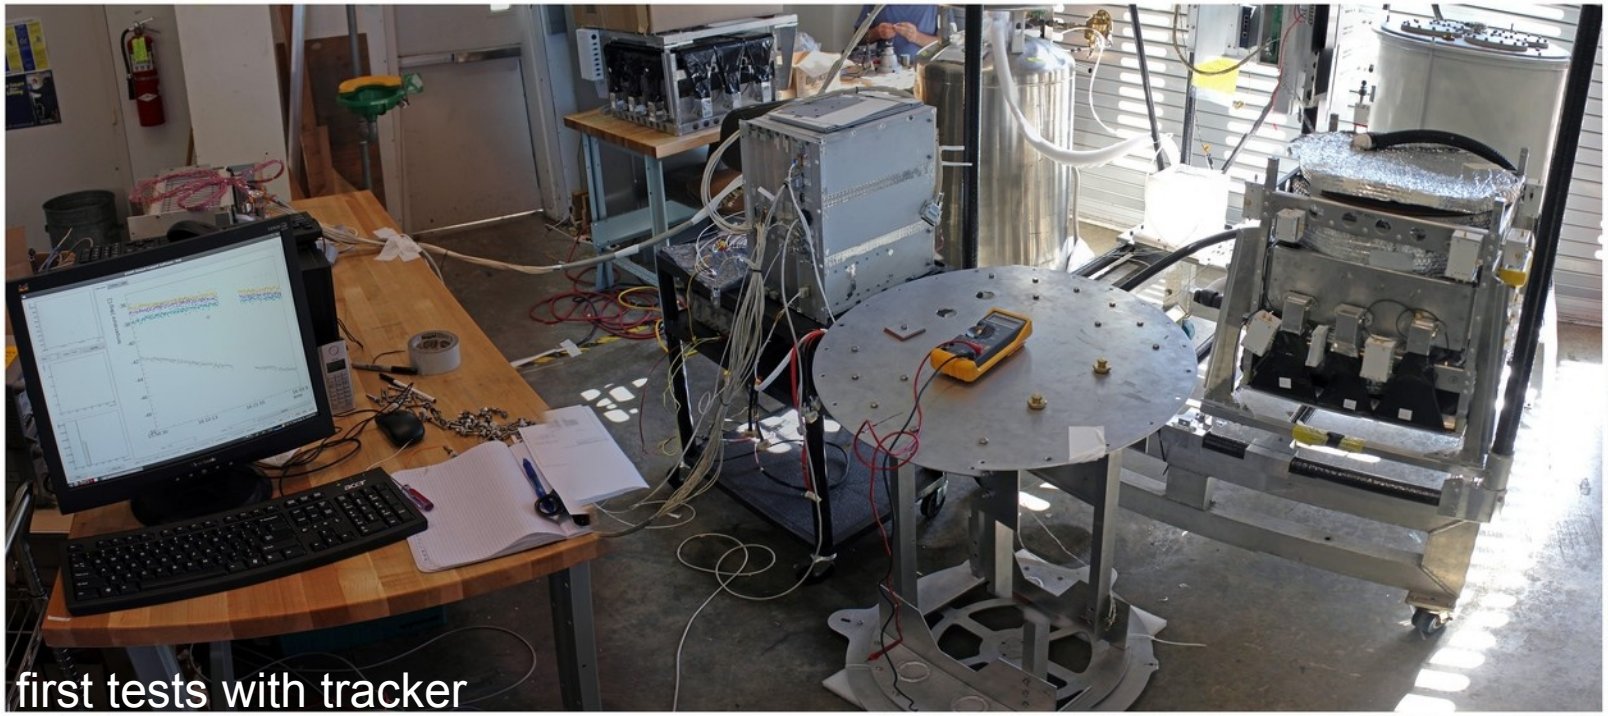
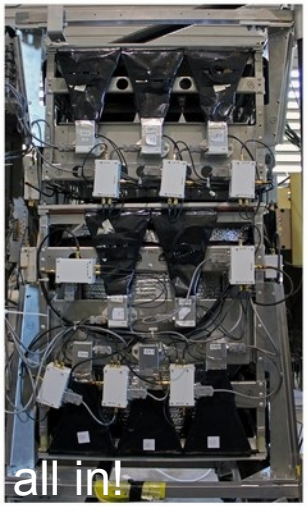
soldering job

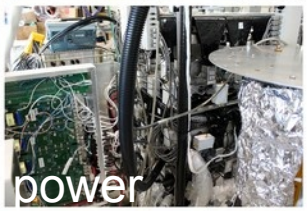
paint job



first tests with tracker

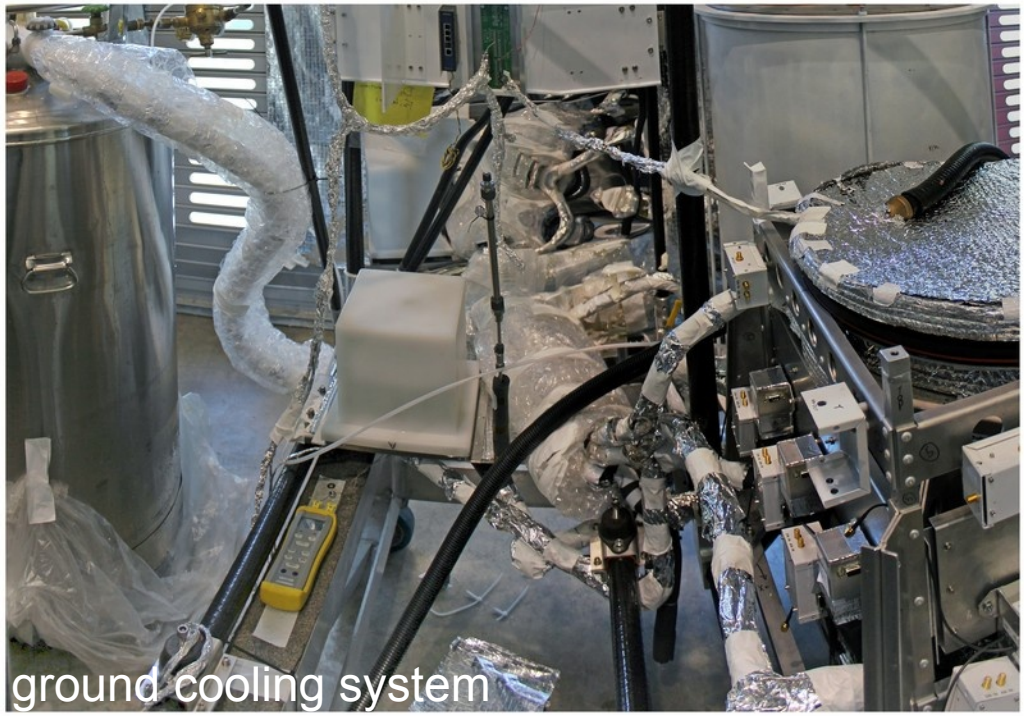


all in!



power

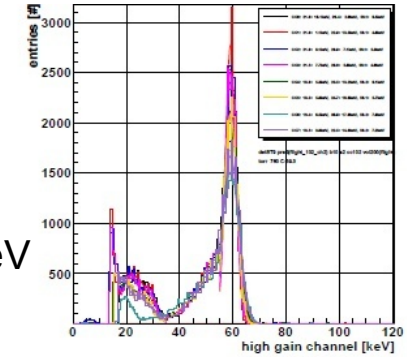
integrated tracker

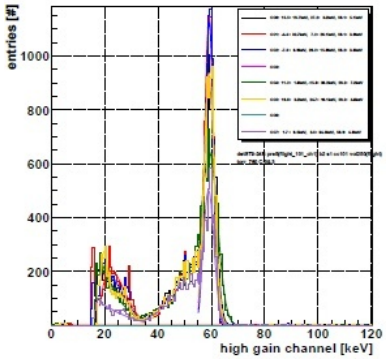


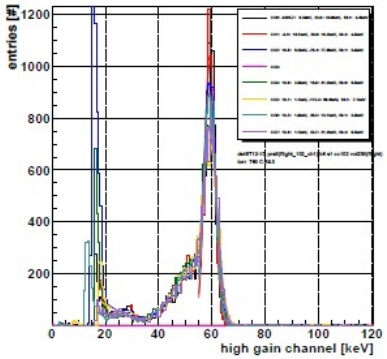
ground cooling system

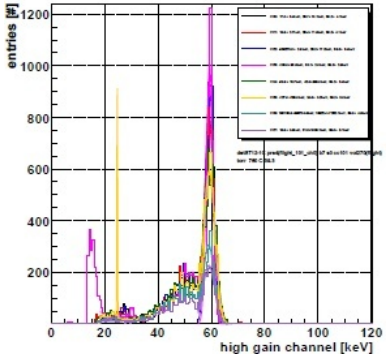
First tracker results

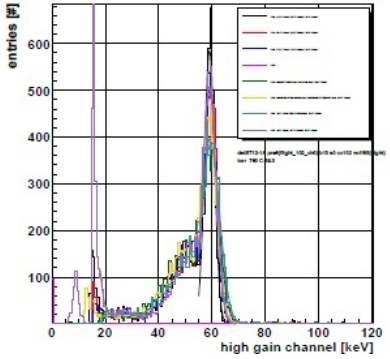
Am241:
- FWHM of 59.5keV line: (5.6±1.4)keV
- minimum energy: ~15keV



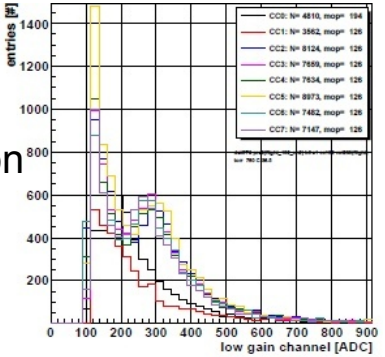


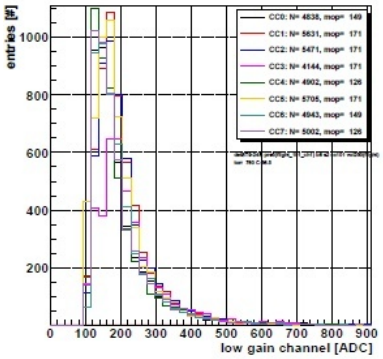


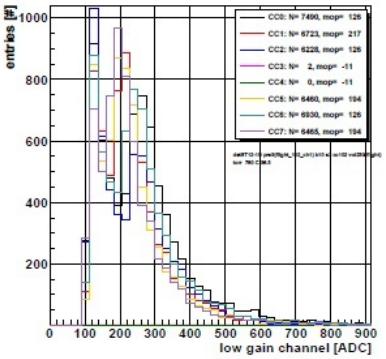


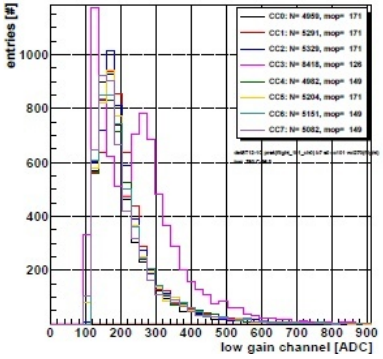


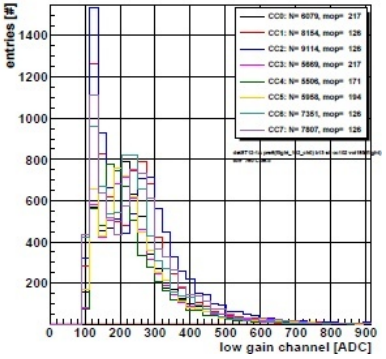
Atmospheric muons:
- Landau shape distribution
- MOP value at ~1MeV



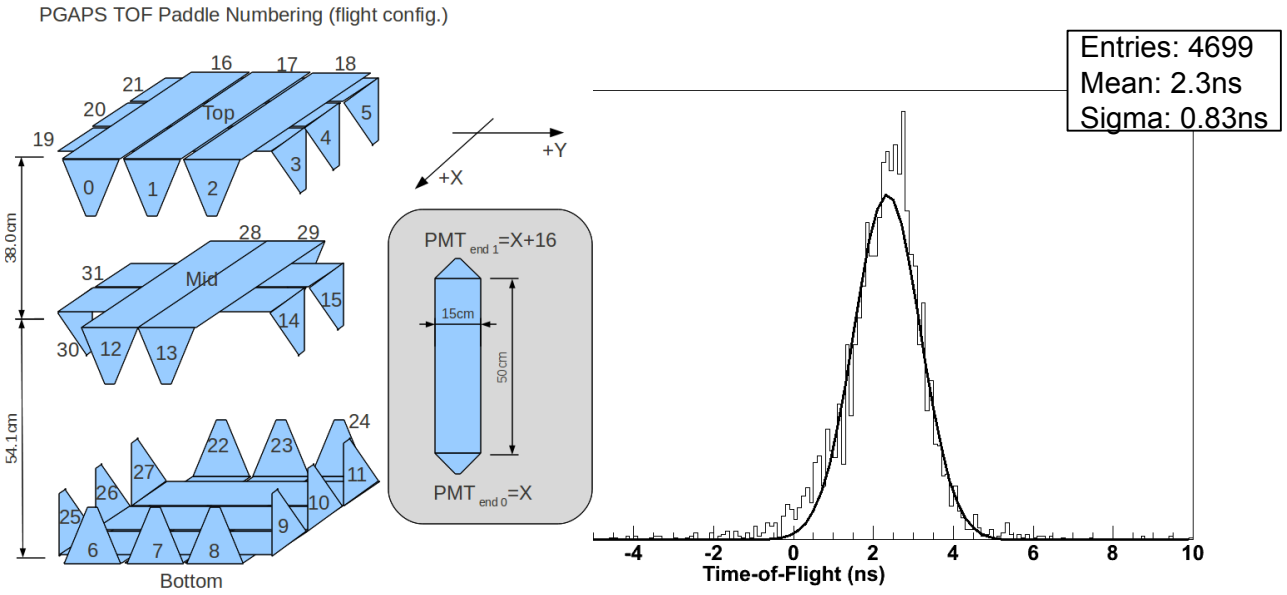


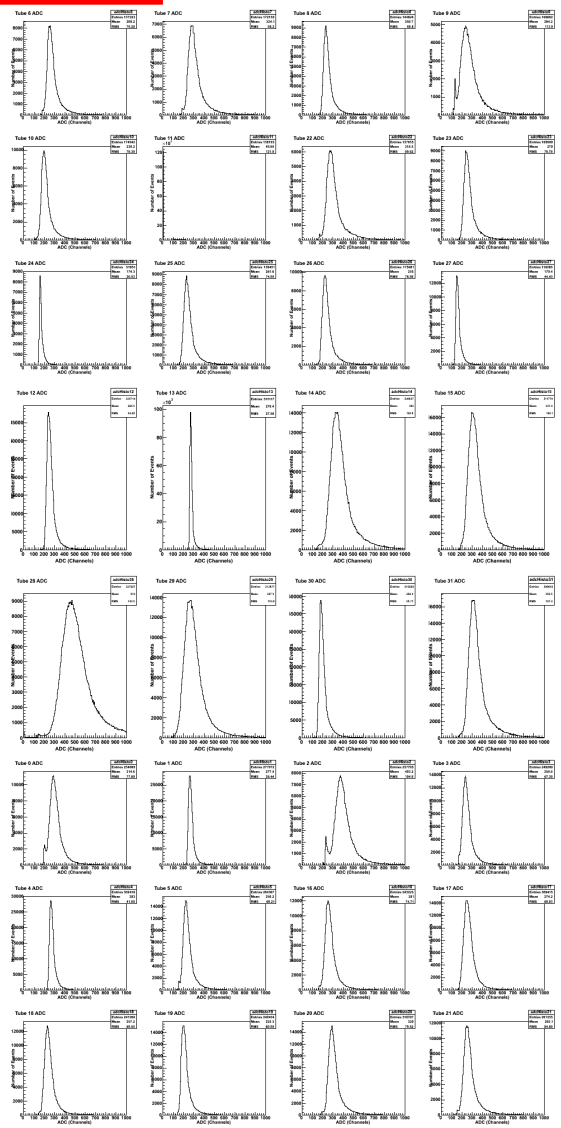






TOF testing

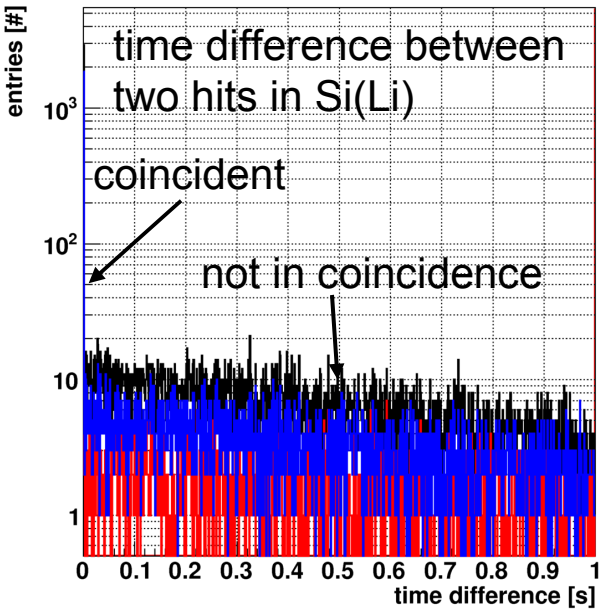


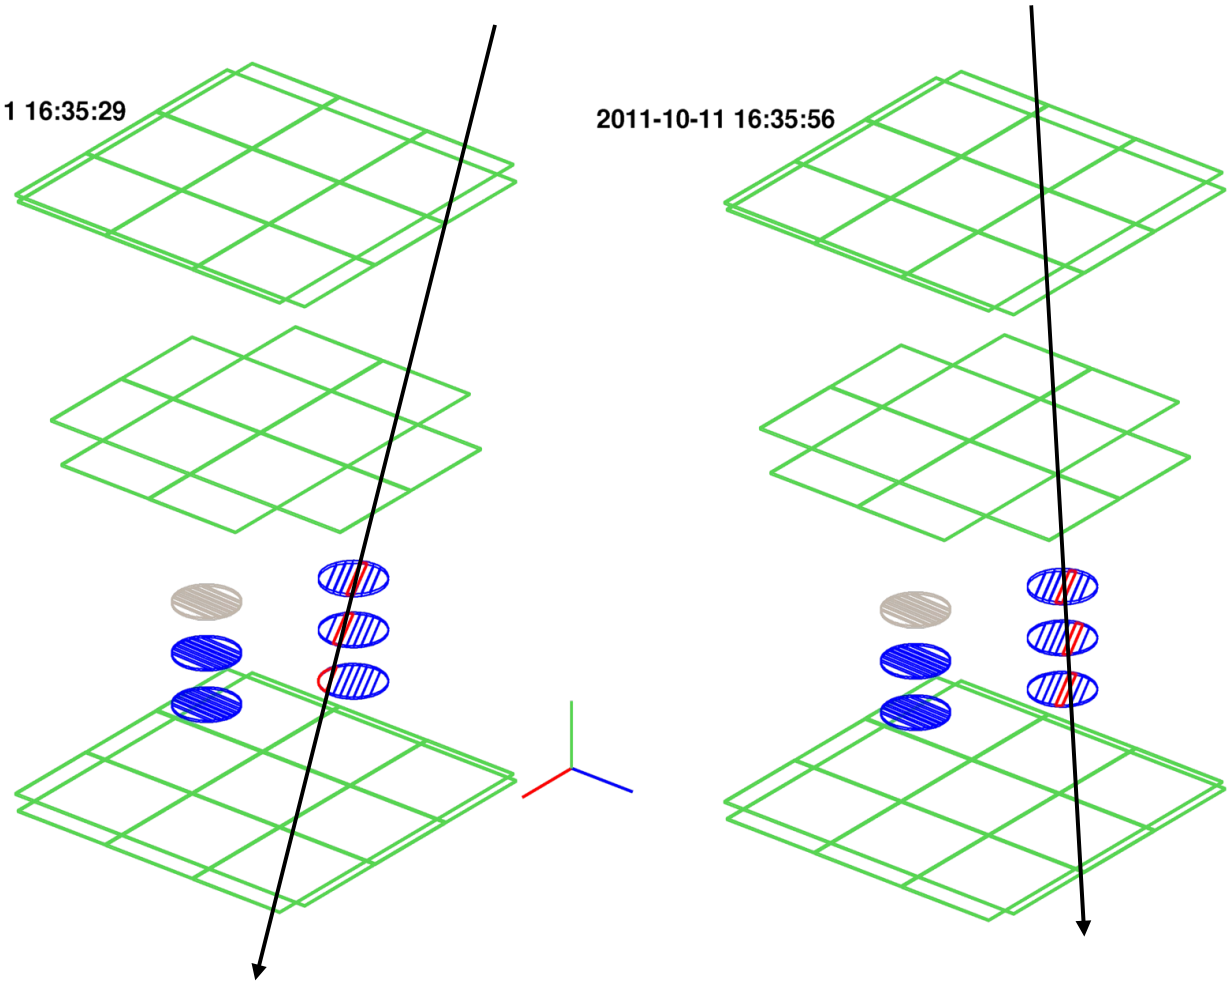


- TOF shows good distributions the energy depositions for each of the 32 tubes
- timing resolution is 590ps per paddle
- tracking resolution of the TOF is of order several cm

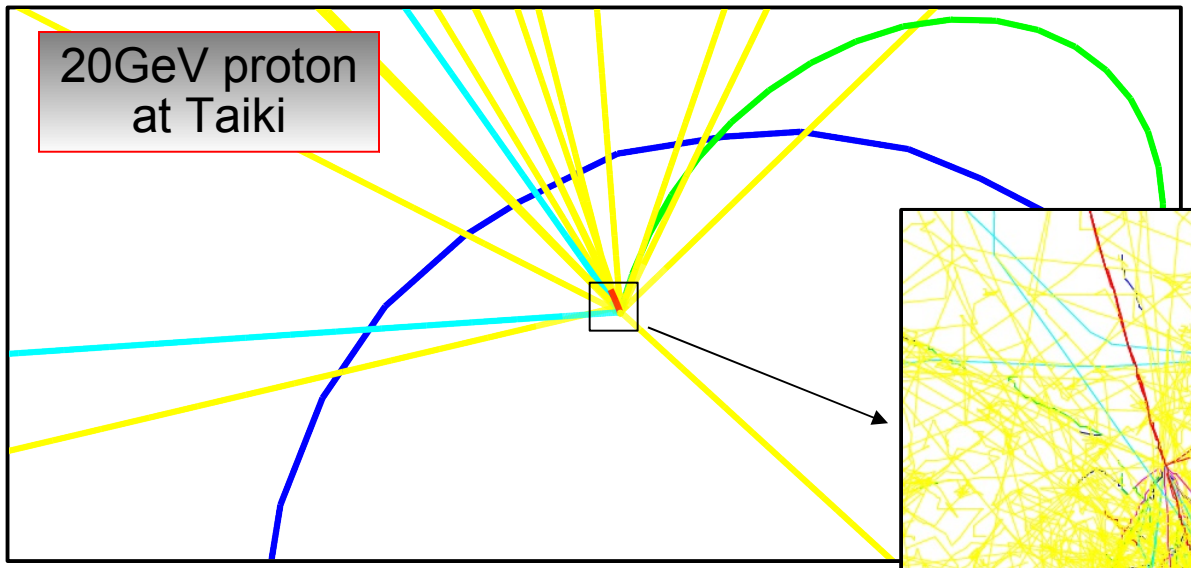
First tracks

- TOF triggered with (T&&M) | (M&&B) the tracker readout
- nicely coincident energy depositons in Si(Li)

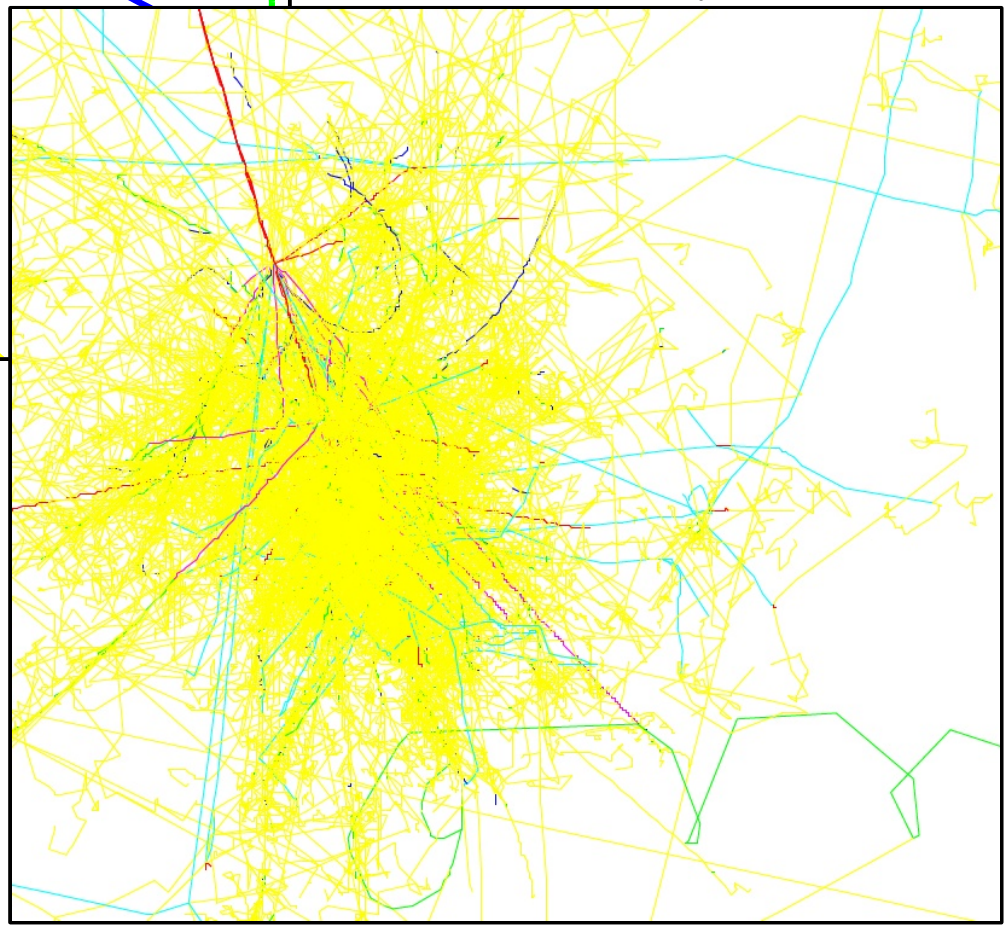




Air shower & geomagnetic field

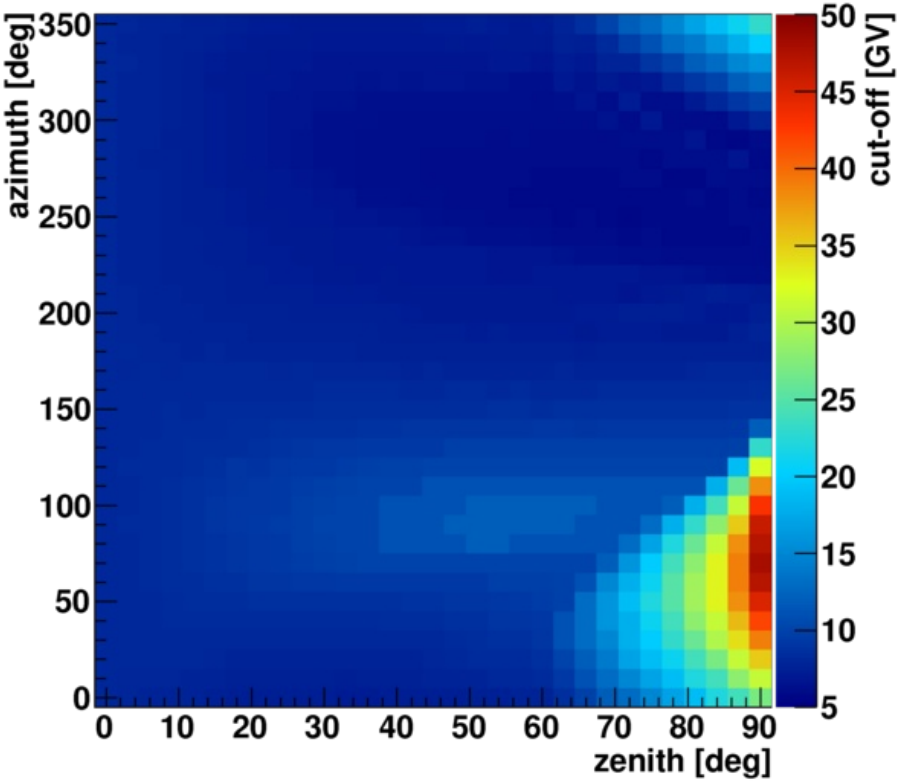


proton > 10MeV (red)
electron > 10MeV (green)
positron > 10MeV (blue)
neutron > 10MeV (turquoise)
muon > 10MeV (purple)
photon > 10keV (yellow)

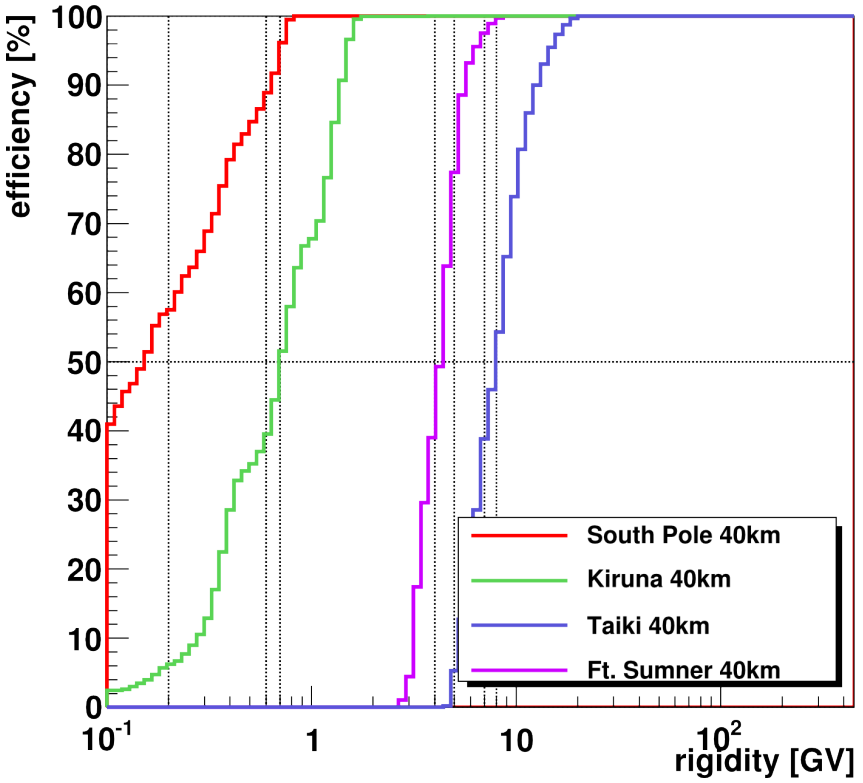


- use of NRLMSISE-00 atmospheric model: models the temperatures and densities of the atmosphere's components.
- grammage of matter in front of 33km: ~8.4g/cm^2 (Space: 6-10g/cm^2)
- on average ~20% of a radiation length (nuclear mean free pathlength ~10%) before 33km: **Atmospheric background has to be calculated!**

Cut-off and particle direction



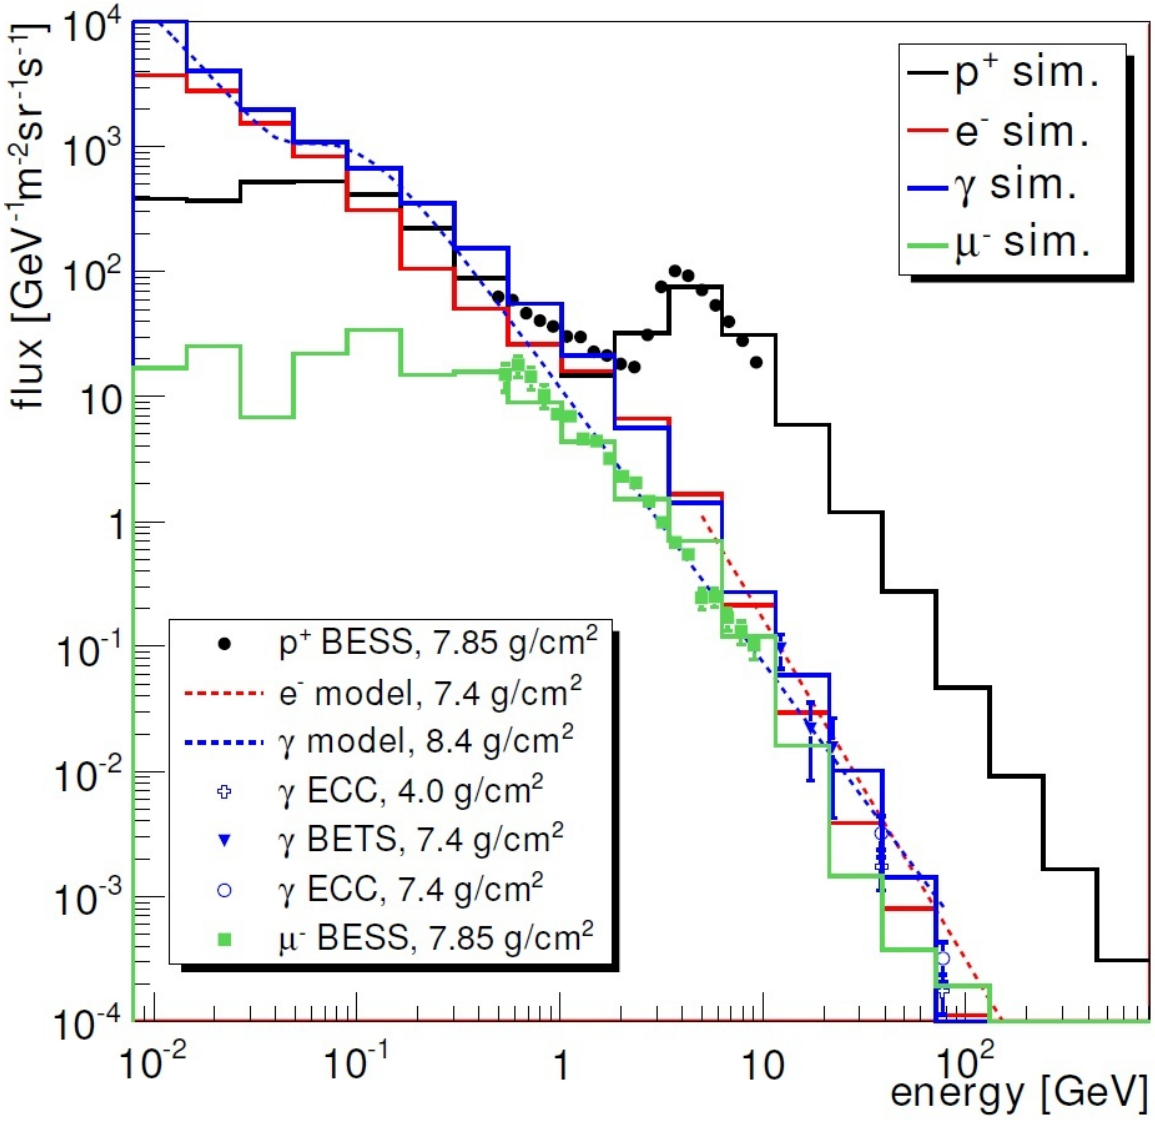
cut-off in Taiki as function of direction

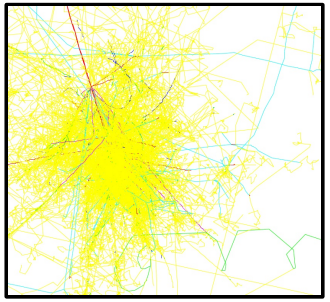


cut-off averaged over isotropic distribution at different positions:

50% of cosmic rays with ~8GV get through to balloon altitude in Taiki

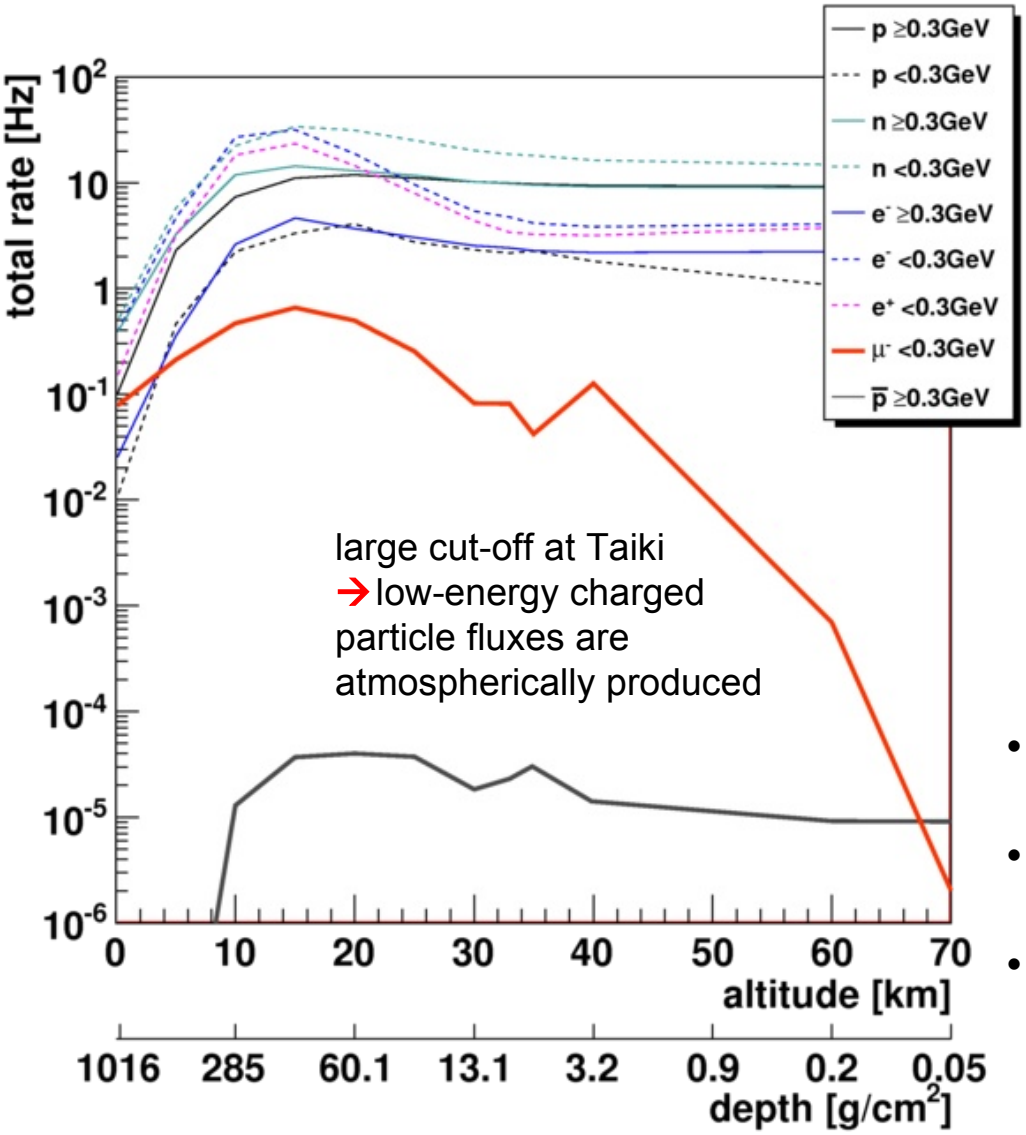
Validation of air shower simulations

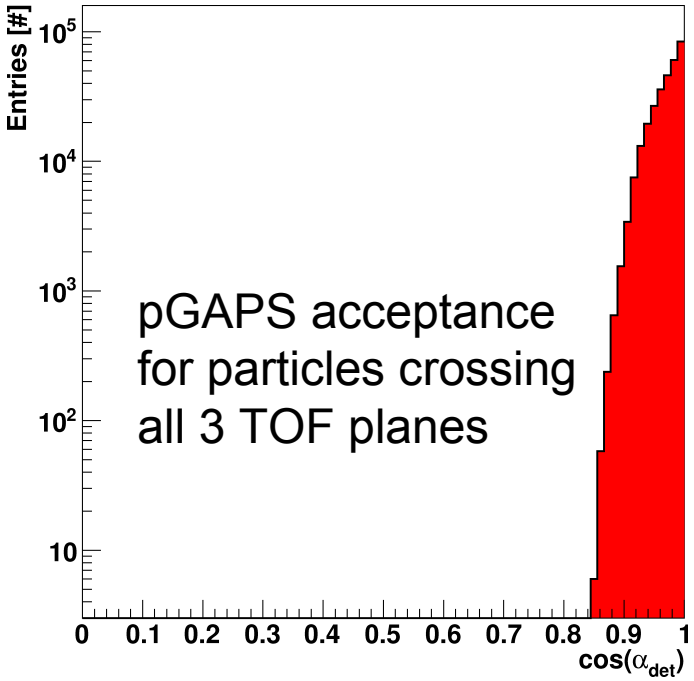




- particle fluxes (ATM+CR) for certain particle types at different altitudes
- comparison of atmospheric simulations shows **good agreement** with BESS, ECC, BETS, PPB-BETS, CAPRICE measurements and models

Particle rates for pGAPS





- particle rate at 33km at Taiki: **total ~30Hz** (accep.: 0.054m²sr)
- strongest backgrounds by neutrons, protons, electrons, positrons
- no antiprotons will be measured, but muons might be used to create muonic atoms to study exotic physics at flight

Conclusion and outlook

- measurement of low-energetic antideuteron flux is a promising way for indirect dark matter search
- GAPS is specifically designed for low-energetic antideuterons with a unique detection technique using the creation of exotic atoms
- GAPS is planned to have (U)LDB flights from South Pole starting from 2016
- prototype experiment is currently under test and a flight is planned for spring 2012 from Taiki, Japan

BESS & AMS-02 antideuterons

- BESS and AMS-02 use magnetometers for the antideuteron measurements
- protons are a huge source of background taking the momentum resolution of the tracker into account
