Cosmic rays as messengers

Cosmic rays 2016

Existence of dark matter

Bullet cluster

red: hot X-ray emitting gas

blue: distribution of dark matter

- **dark matter exists, but nature remains unknown!**
- luminous matter cannot describe the structure of the Universe
- evidence for dark matter comes from many different type of observations on different distance scales

Why do we need something new?

- dark matter is so far only gravitationally visible and must be a **new non-baryonic type of particle**
 - neutral
 - with relatively high mass to explain the structure formation of the universe
 - with only very weak interactions with standard particles (if at all)
- **discovering the nature of dark matter is one of the most striking problems in physics**

How is dark matter interacting?

- **natural assumption:** dark matter was in thermal equilibrium in the early universe expansion led to dark matter freeze-out
- **WIMP miracle:** weak-scale particles are ideal candidates ($\sim 100\text{-}1000\text{GeV}$) to reproduce observed relic dark matter density

→ dark matter must(?) be able to interact with standard model particles

Direct dark matter searches (scattering)

- **direct dark matter search:** measure cross-section via nuclear recoil
- typically large, heavy and very pure target materials in deep mines (~10 operating experiments)
- experiments start to reach in theoretically preferred parameter space
- **experiments disagree** → some experiments claim discovery, some set exclusion limits

Dark matter signal in cosmic rays?

Cosmic rays from dark matter annihilation or decay could contribute to the astrophysical cosmic rays

- unexplained features in positrons
- proposed theories:
 - astrophysical origin → pulsars
 - SNR acceleration
 - **dark matter annihilation**
- **no (?) excess for antiprotons → inconclusive**

Galactic gamma-ray excess

Uncovering a gamma-ray excess at the galactic center

Unprocessed map of 1.0 to 3.16 GeV gamma rays

Known sources removed

Galactic gamma-ray excess

gamma-ray

antiproton

- gamma-ray excess at the galactic center $\rightarrow$ $\sim 30 \text{ GeV}$ dark matter particle?
- signal in low-energy antiprotons?
- understanding of astrophysical background is a big challenge

Dark matter interactions

Berlin, Hooper, McDermott: Phys. Rev. D 89, 115022 (2014)

Model Number	DM	Mediator	Interactions	Elastic Scattering	Near Future Reach?	
					Direct	LHC
1	Dirac Fermion	Spin-0	$\bar{\chi}\gamma^5\chi, \bar{f}f$	$\sigma_{\text{SI}} \sim (q/2m_\chi)^2$ (scalar)	No	Maybe
1	Majorana Fermion	Spin-0	$\bar{\chi}\gamma^5\chi, \bar{f}f$	$\sigma_{\text{SI}} \sim (q/2m_\chi)^2$ (scalar)	No	Maybe
2	Dirac Fermion	Spin-0	$\bar{\chi}\gamma^5\chi, \bar{f}\gamma^5f$	$\sigma_{\text{SD}} \sim (q^2/4m_n m_\chi)^2$	Never	Maybe
2	Majorana Fermion	Spin-0	$\bar{\chi}\gamma^5\chi, \bar{f}\gamma^5f$	$\sigma_{\text{SD}} \sim (q^2/4m_n m_\chi)^2$	Never	Maybe
3	Dirac Fermion	Spin-1	$\bar{\chi}\gamma^\mu\chi, \bar{b}\gamma_\mu b$	$\sigma_{\text{SI}} \sim \text{loop (vector)}$	Yes	Maybe
4	Dirac Fermion	Spin-1	$\bar{\chi}\gamma^\mu\chi, \bar{f}\gamma_\mu\gamma^5f$	$\sigma_{\text{SD}} \sim (q/2m_n)^2$ or $\sigma_{\text{SD}} \sim (q/2m_\chi)^2$	Never	Maybe
5	Dirac Fermion	Spin-1	$\bar{\chi}\gamma^\mu\gamma^5\chi, \bar{f}\gamma_\mu\gamma^5f$	$\sigma_{\text{SD}} \sim 1$	Yes	Maybe
5	Majorana Fermion	Spin-1	$\bar{\chi}\gamma^\mu\gamma^5\chi, \bar{f}\gamma_\mu\gamma^5f$	$\sigma_{\text{SD}} \sim 1$	Yes	Maybe
6	Complex Scalar	Spin-0	$\phi^\dagger\phi, \bar{f}\gamma^5f$	$\sigma_{\text{SD}} \sim (q/2m_n)^2$	No	Maybe
6	Real Scalar	Spin-0	$\phi^2, \bar{f}\gamma^5f$	$\sigma_{\text{SD}} \sim (q/2m_n)^2$	No	Maybe
6	Complex Vector	Spin-0	$B_\mu^\dagger B^\mu, \bar{f}\gamma^5f$	$\sigma_{\text{SD}} \sim (q/2m_n)^2$	No	Maybe
6	Real Vector	Spin-0	$B_\mu B^\mu, \bar{f}\gamma^5f$	$\sigma_{\text{SD}} \sim (q/2m_n)^2$	No	Maybe
7	Dirac Fermion	Spin-0 (t-ch.)	$\bar{\chi}(1 \pm \gamma^5)b$	$\sigma_{\text{SI}} \sim \text{loop (vector)}$	Yes	Yes
7	Dirac Fermion	Spin-1 (t-ch.)	$\bar{\chi}\gamma^\mu(1 \pm \gamma^5)b$	$\sigma_{\text{SI}} \sim \text{loop (vector)}$	Yes	Yes
8	Complex Vector	Spin-1/2 (t-ch.)	$X_\mu^\dagger\gamma^\mu(1 \pm \gamma^5)b$	$\sigma_{\text{SI}} \sim \text{loop (vector)}$	Yes	Yes
8	Real Vector	Spin-1/2 (t-ch.)	$X_\mu\gamma^\mu(1 \pm \gamma^5)b$	$\sigma_{\text{SI}} \sim \text{loop (vector)}$	Yes	Yes

TABLE V. A summary of the simplified models identified in our study as capable of generating the observed gamma-ray excess without violating the constraints from colliders or direct detection experiments. In the last two columns, we indicate whether the model in question will be within the reach of near future direct detection experiments (LUX, XENON1T) or of the LHC. Models with an entry of “Never” predict an elastic scattering cross section with nuclei that is below the irreducible background known as the “neutrino floor”. The “Model Number” given in the first column provides the key for the model points shown in Fig. 9.

Depends on

- type of DM: scalar, fermion, vector
- type of coupling: scalar (1), pseudoscalar (γ^5), vector (γ^μ), axial ($\gamma^\mu\gamma^5$)

Antideuterons

- deuterons are the nuclei of heavy water and antideuterons are the corresponding antimatter ($q=-1, m=1876\text{MeV}, s=1$)
- antideuterons were discovered in 1965 at CERN and Brookhaven and were the **first real (bound) antimatter ever discovered**
- seen since then at, e.g., LEP, Tevatron, LHC collider experiments
- **have never been discovered in cosmic rays**
(next antinucleus in line after the antiproton and before antihelium)

Status of cosmic-ray antideuterons

Review of the theoretical and experimental status of dark matter identification with cosmic-ray antideuterons

Examples for beyond-standard-model Physics:

Neutralino:
SUSY lightest supersymmetric particle, decay into $b\bar{b}$, compatible with signal from Galactic Center measured by Fermi

late decays of unstable gravitinos

astrophysical background: collisions of protons and antiprotons with interstellar medium

+ models with heavy dark matter

Antideuterons are the most important unexplored indirect detection technique!

Uncertainties

Antideuteron formation

dark matter

conventional production
(e.g., p+ISM) & dark matter

- $\bar{d}$ can be formed by an $\bar{p}\bar{n}$ pair if coalescence momentum p_0 is small

$$\frac{dN_{\bar{d}}}{dT_{\bar{d}}} = \frac{p_0^3}{6} \frac{m_{\bar{d}}}{m_{\bar{n}}m_{\bar{p}}} \frac{1}{\sqrt{T_{\bar{d}}^2 + 2m_{\bar{d}}T_{\bar{d}}}} \frac{dN_{\bar{n}}}{dT_{\bar{n}}} \frac{dN_{\bar{p}}}{dT_{\bar{p}}}$$

- important differences for different experiments and MC generators exist $\rightarrow$ more data would help**

(Anti)deuterons and NA61/SHINE

- cosmic ray production happens between 40 and 400 GeV → SPS energies from 9 to 400 GeV are ideal
- we are working on (anti)deuteron and antiproton analysis

NA49 antideuteron

- NA49 is pre-decessor experiment
- NA49 lead-lead data were already analyzed for antideuterons
- important cross-check for the MC generators: measurement of the yield of antiprotons with the same data

T. Anticic et al., Phys. Rev. C 85, 044913 (2012)

Propagation uncertainty

- propagation is the strongest uncertainty source for primary antideuteron:
halo size for diffusion calculation poorly constrained
- more data on various nuclear species are needed for better constraints

Solar modulation

Geomagnetic cutoff

Red: 0.5GV
Blue: 1.0GV
Magenta: 1.5GV
Green: 2.0GV
Cyan: 2.5GV

Reverse computation of antiproton trajectories starting at the same location in the same direction for two different times

→ magnetic environment change changes the trajectories drastically and influences the cutoff values

Geomagnetic cutoff

Geomagnetic cutoff for AMS-02 and GAPS

- geomagnetic environment is influenced by solar activity
- AMS-02 is installed on the ISS (latitude $\pm 52^\circ$)
 - understanding of geomagnetic environment crucial for low energies
- GAPS is planned to fly from Antarctica ($\sim -80^\circ$)
 - geomagnetic corrections are minimal

Solar flare event: 7-March-2012

Extreme UV flash of X5-class solar flare March 7, 2012. (NASA SDO)

**Significant decrease of
geomagnetic cutoff**

Magnetic field changes since 2011

Geant4 - Model for $\bar{d}$ simulation

- recent implementation in Geant4: antideuteron simulations
- FTF model (diffractive string excitation with momentum transfer) was extended to handle nucleus-nucleus interaction down to 0GeV
- best model for antiprotons, antineutrons, antideuterons:
 - very little data for validation available
 - needed:
 - antideuteron formation
 - exotic model for antiproton and antideuteron (GAPS)

Identification challenge

Required rejections for antideuteron detection:

- **protons**: $> 10^8 - 10^{10}$
- **He-4**: $> 10^7 - 10^9$
- **electrons**: $> 10^6 - 10^8$
- **positrons**: $> 10^5 - 10^7$
- **antiprotons**: $> 10^4 - 10^6$

Antideuteron measurement with balloon and space experiments require:

- **strong background suppression**
- **long flight time and large acceptance**

AMS-02 on the International Space Station

- AMS is a multi-purpose particle physics detector installed on the International Space Station
- large international collaboration (~600 people from 60 countries involved)
- AMS collected 10th of billions of events since May 2011

AMS sub-detectors

TRD
identify e^+, e^-

Silicon tracker
charge, momentum

ECAL
energy of e^+, e^-, γ

TOF
charge, velocity

magnet
charge sign

RICH
charge, velocity

Charge and momentum/energy are measured independently by the tracker, RICH, TOF and ECAL

AMS antideuteron analysis

	e ⁻	p	He, Li, Be, ... Fe	γ	e ⁺	$\bar{p}, \bar{d}$	$\overline{\text{He}}, \overline{\text{C}}$
TRD γ=E/m							
TOF dE/dx, velocity							
Tracker dE/dx, momentum							
RICH precise velocity							
ECAL shower shape, energy det							

- antideuteron identification:**

- momentum measured in the form of rigidity
- charge from TOF, TRD, tracker
- lower velocities: **T**ime **O**f **F**light scintillator system
- higher velocities: **R**ing **I**mage **C**herenkov detector

$$m = R \cdot Z \sqrt{\frac{1}{\beta^2} - 1}$$

- self-calibrated analysis:**

- calibrate antideuteron analysis with deuterons and antiprotons (simulations and data)
- geomagnetic cut-off location is challenging: study low-energy protons and electrons to calibrate geomagnetic and solar effects

Example for proton and deuteron mass reconstruction

Deuterons are interesting, too

- available deuteron measurements have mostly large error bars
- RICH energy range (~ 1 - $9\text{GeV}/n$) will be important to constrain propagation models
- d/p , $d/\text{He-4}$, $d/\text{He-3}$ ratios are very important to understand cosmic-ray propagation

The GAPS experiment

Columbia U, UC Berkeley
UCLA, U Hawaii,
Haverford

- the **General AntiParticle Spectrometer** is especially designed for **low-energy antideuteron and antiprotons**
- identification by stopping and creation of an exotic atom
[KEK testbeam measurements → Astropart. Phys. 49, 52 (2013)]
- LDB flights from Antarctica

Background rejection:

- stopping protons don't have enough energy to produce pions and cannot form exotic atoms (pos. charge)
- deexcitation X-rays have characteristic energies
- number of annihilation pions and protons
- stopping depth in detector

GAPS antiproton

Predicted primary antiproton fluxes at TOA from neutralinos, LZPs, gravitinos, or PBHs, along with neutralino signals as seen by 1 GAPS LDB flight

Prototype GAPS

Goals:

- demonstrate stable operation of the detector components during flight
- study Si(Li) cooling approach for thermal model
- measure background levels

2012-06-03 08:10:11
altitude 32.4km
mean TRK T -18.4C

2012:06:03 02:28:16

pGAPS flight: June 3rd 2012 from Taiki, Japan

preparations 4:36am

release of balloon

4:55am

**take
off**

return to the harbor 1:05pm

- **well defined TOF trigger and tracker runs**
 - time: 19×13min
 - ~600,000 triggers
- **carry out in-flight calibration of Si(Li) detectors**
 - run X-ray tube
 - time: 13×4min
- **trigger on Si(Li) detectors to study incoherent X-ray background**
 - time: 9×3min

pGAPS flux measurement

total flux vs. altitude

flux vs. β at 33km

particle composition at 33km

- flux at drift-out “boomerang” altitude (10-15km) is $\sim 30\%$ higher than at float (33km)
- flux as function of velocity compared to simulations with Geant4+PLANETOCOSMICS (incl. geomagnetic, atmospheric effect)
 - $\beta < 0.2$ ($E_{\text{kin,proton}} \sim 20\text{MeV}$) very good agreement
 - $\beta = 0.3-0.5$ ($E_{\text{kin,proton}} \sim 50-150\text{MeV}$) within systematic errors
 - $\beta > 0.7$ ($E_{\text{kin,proton}} \sim 400\text{MeV}$) good agreement
 - deviations at 0.3 and 0.6 visible $\rightarrow$ more simulation work at low energies in the future
- α particles constitute about $\sim 10\%$ of the flux at 33km ($\sim 9\text{g}/\text{cm}^2$) $\rightarrow$ in good agreement with BESS data

Path forward

- antideuteron searches are experimentally challenging
→ **multiple experiments for cross-checks are important**
- AMS-02 and GAPS have very different event signatures **AND** very different backgrounds
→ **very good for independent confirmation**
- two independent flight trajectories
 - AMS-02 has a factor of 10 geomagnetic cutoff correction
 - GAPS analysis has nearly no geomagnetic correction
- **low-energy antiproton flux measurement will be the most important cross-check between AMS-02 and GAPS**

GAPS from Antarctica

Conclusion & Outlook

- Measurement of antideuteron is a promising way for indirect dark matter search
- AMS-02 and GAPS have for the first time sensitivity to antideuteron from dark matter annihilation or decay
- Extended models and improved simulation tools needed
- Measurements with NA61/SHINE will improve understanding of antideuteron production and modeling

GAPS from Antarctica
